### Clot-retrieval no better for strokes

Recovery after stroke is not improved by using a device to retrieve the clot, a US study suggests.

In a trial of more than 650 patients, standard clot-busting drugs were just as effective as using surgery to clear blockages directly.

The University of Cincinnati-led study was stopped early after it became clear that risky procedures to remove clots were having little impact.

Experts said more work was needed over clot-retrieval devices.

Presenting the findings at the International Stroke Conference, researchers said that 39% of patients treated with a clot-busting drug were living independently after 90 days.

More than 650 patients were studied

## Design and Validation of a Prehospital Stroke Scale to Predict Large Arterial Occlusion The Rapid Arterial Occlusion Evaluation Scale

**Background and Purpose**—We aimed to develop and validate a simple prehospital stroke scale to predict the presence of large vessel occlusion (LVO) in patients with acute stroke.

**Methods**—The Rapid Arterial Occlusion Evaluation (RACE) scale was designed based on the National Institutes of Health Stroke Scale (NIHSS) items with a higher predictive value of LVO on a retrospective cohort of 654 patients with acute ischemic stroke: facial palsy (scored 0–2), arm motor function (0–2), leg motor function (0–2), gaze (0–1), and aphasia or agnosia (0–2). Thereafter, the RACE scale was validated prospectively in the field by trained medical emergency technicians in 357 consecutive patients transferred by Emergency Medical Services to our Comprehensive Stroke Center. Neurologists evaluated stroke severity at admission and LVO was diagnosed by transcranial duplex, computed tomography, or MR angiography. Receiver operating curve, sensitivity, specificity, and global accuracy of the RACE scale were analyzed to evaluate its predictive value for LVO.

**Results**—In the prospective cohort, the RACE scale showed a strong correlation with NIHSS ( $r=0.76$ ;  $P<0.001$ ). LVO was detected in 76 of 357 patients (21%). Receiver operating curves showed a similar capacity to predict LVO of the RACE scale compared with the NIHSS (area under the curve 0.82 and 0.85, respectively). A RACE scale  $\geq 5$  had sensitivity 0.85, specificity 0.68, positive predictive value 0.42, and negative predictive value 0.94 for detecting LVO.

**Conclusions**—The RACE scale is a simple tool that can accurately assess stroke severity and identify patients with acute stroke with large artery occlusion at prehospital setting by medical emergency technicians. (*Stroke*. 2014;45:87-91.)

# RACE Scale

## (0-9)

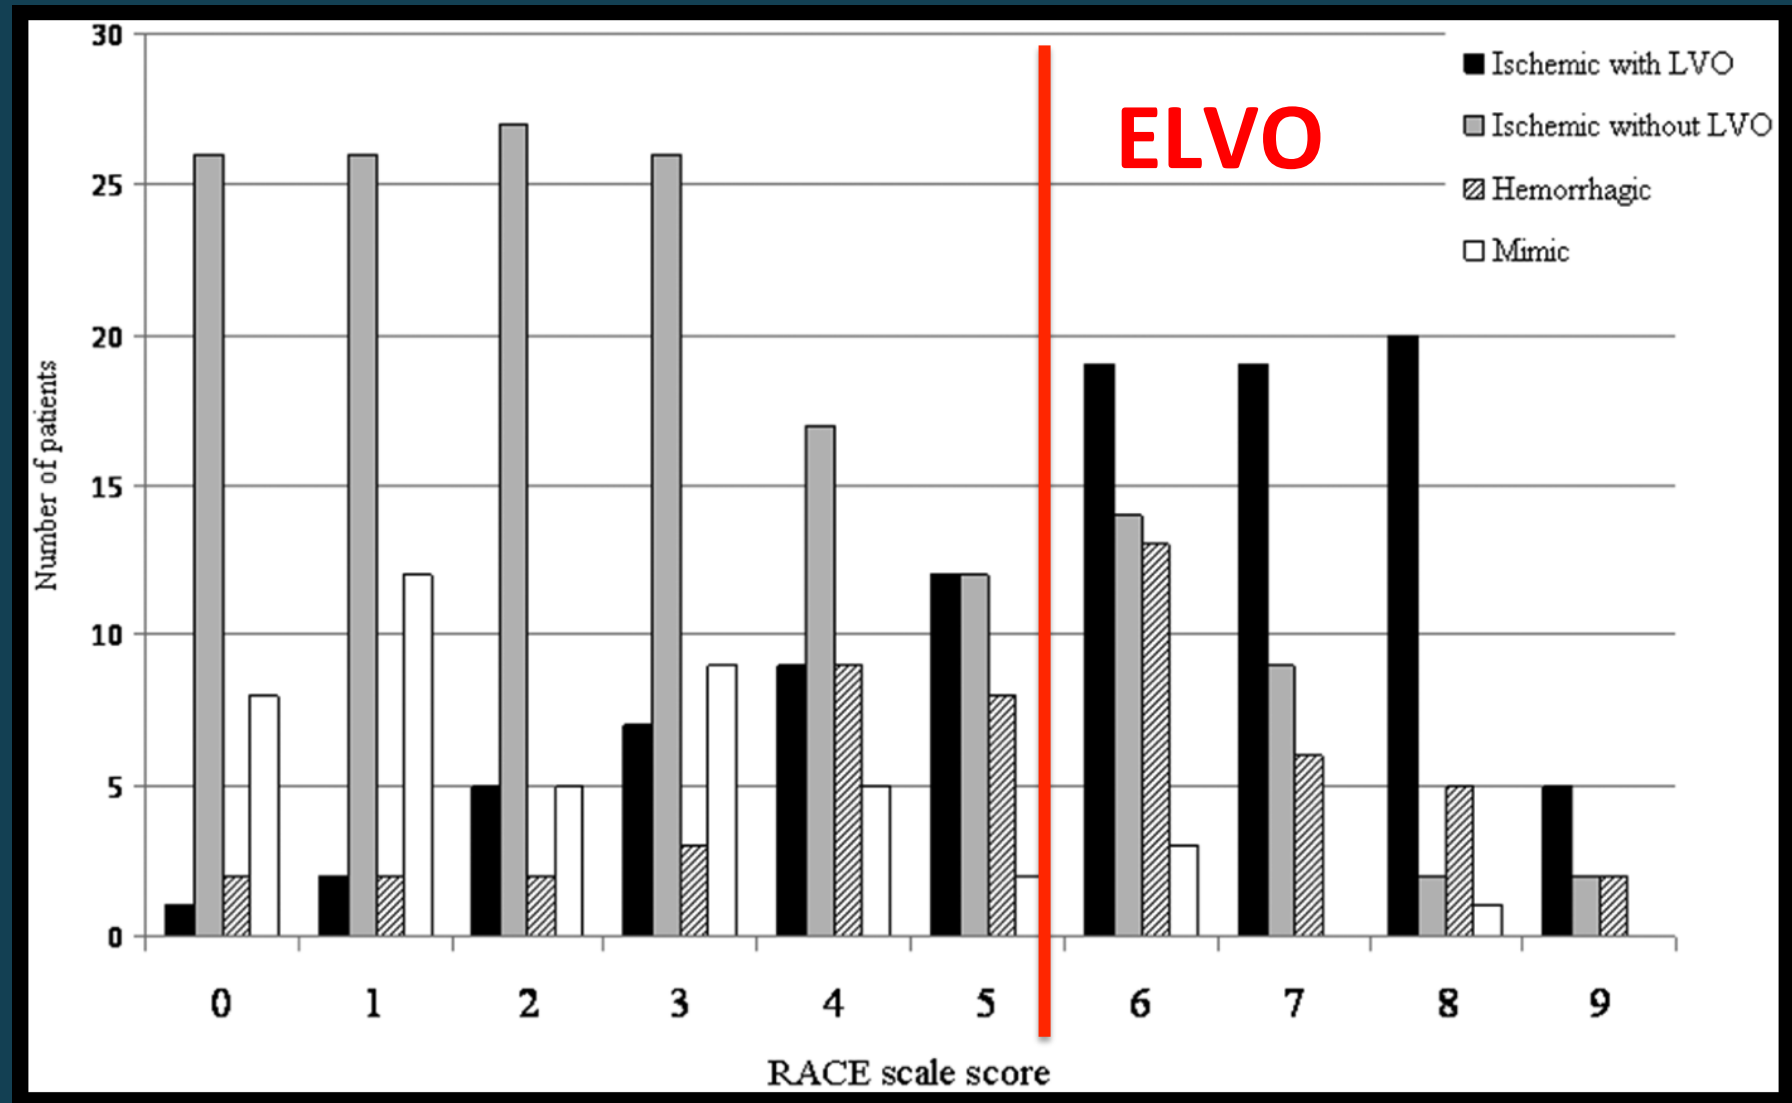

Cortical signs

**Table 1. RACE Scale**

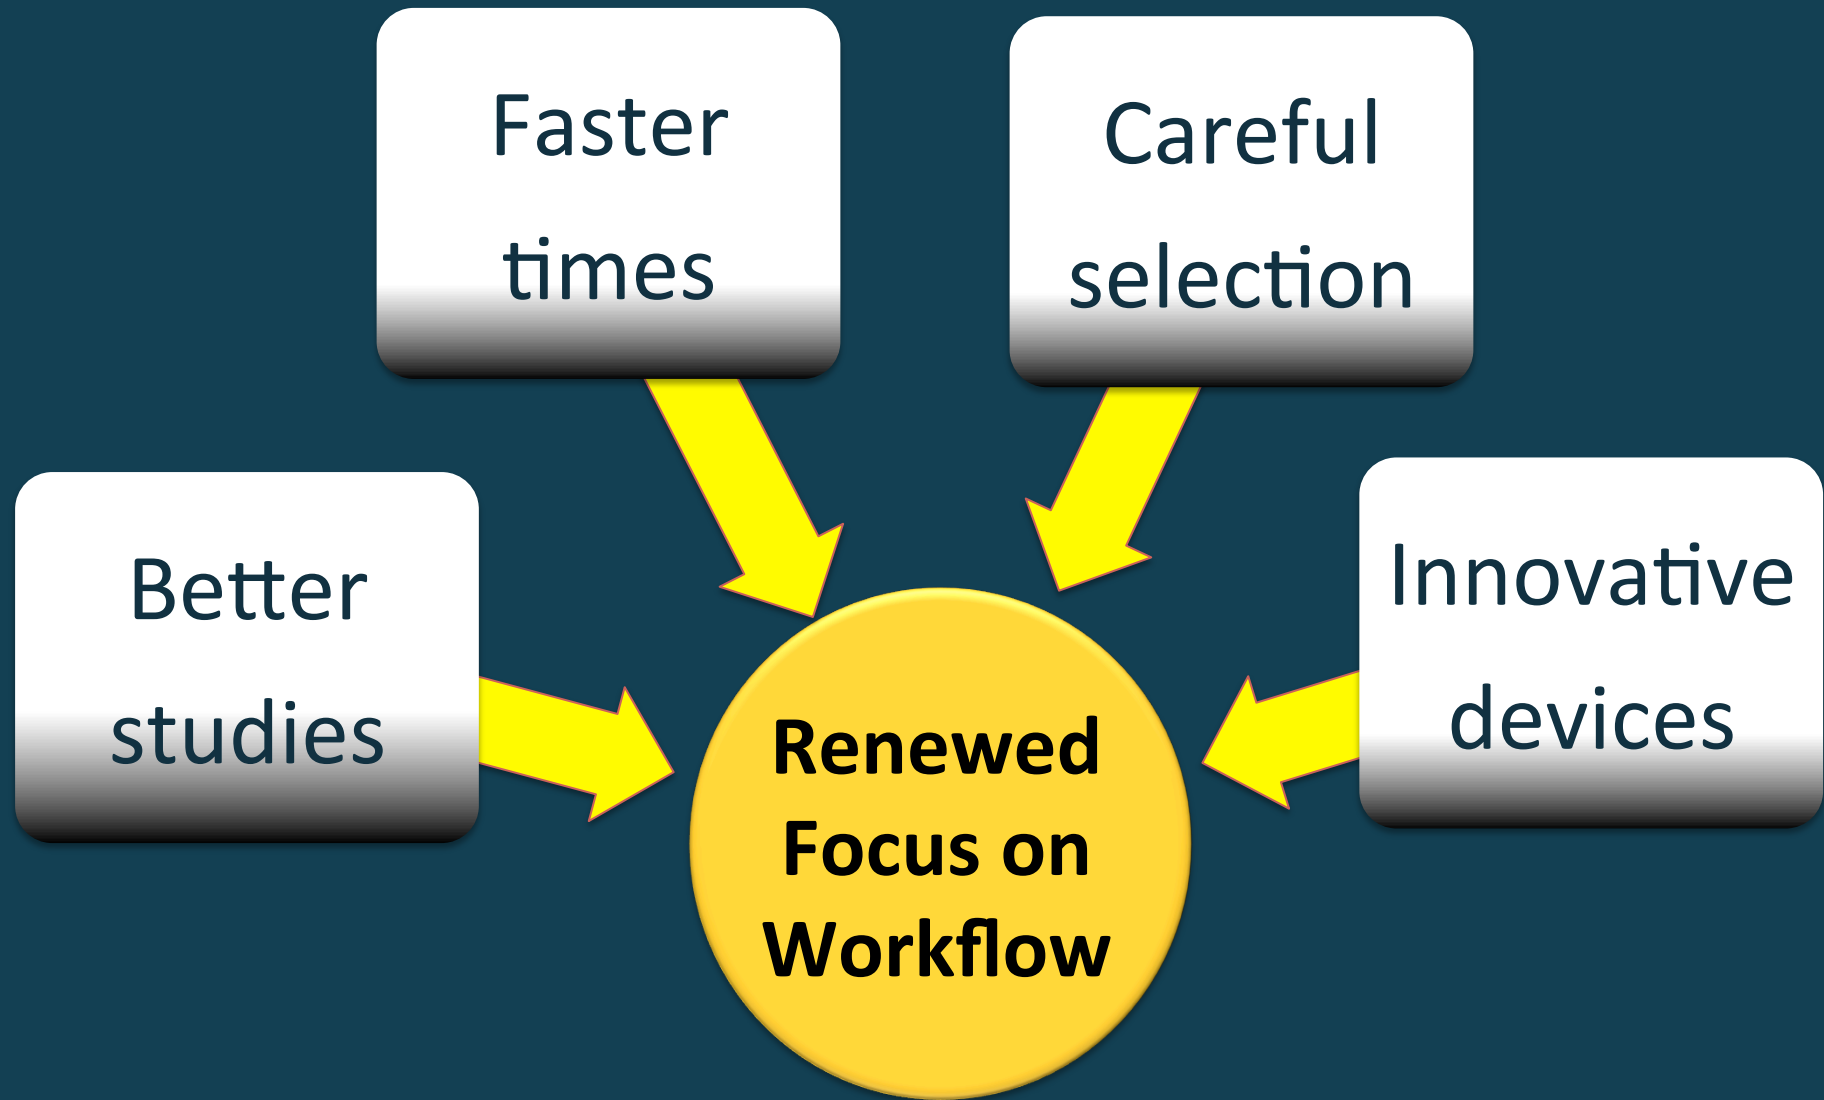

Item	RACE Score	NIHSS Score Equivalence
Facial palsy		
Absent	0	0
Mild	1	1
Moderate to severe	2	2–3
Arm motor function		
Normal to mild	0	0–1
Moderate	1	2
Severe	2	3–4
Leg motor function		
Normal to mild	0	0–1
Moderate	1	2
Severe	2	3–4
Head and gaze deviation		
Absent	0	0
Present	1	1–2
Aphasia* (if right hemiparesis)		
Performs both tasks correctly	0	0
Performs 1 task correctly	1	1
Performs neither tasks	2	2
Agnosia† (if left hemiparesis)		
Patient recognizes his/her arm and the impairment	0	0
Does not recognized his/her arm or the impairment	1	1
Does not recognize his/her arm nor the impairment	2	2
Score total	0–9

## EMS STROKE ALERT

### Obtain the following from EMS:

RACE scale (0-9 score) \_\_\_\_\_

Last known well time \_\_\_\_\_

Anticoagulation (warfarin, pradaxa, xarelto, etc.) \_\_\_\_\_

Estimated time of arrival \_\_\_\_\_

### Actions to consider pre-hospital:

1. Alert neurologist on call for all stroke alerts
2. If RACE score >5 alert neurointerventionalist
3. Early cath lab activation = gaze preference + weakness
